SMART GRID COMMUNICATIONS: PLC AND RF CONVERGE

Deploying and operating a smart metering or smart grid network presents many challenges. First among them is selecting a communications technology that delivers the most reliable and cost-effective performance to the greatest number of meters and grid devices. Selecting the best communications technology for 80-90% of the meters is fairly easy; covering the last 10-20% is where the difficulties and costs arise.

In fact, it's not unusual for a utility to spend 20-30% of its time and resources deploying the first 80% of the network, and then spend 70-80% of its time and resources deploying and connecting the last 20% of the network. This is due to difficult meter locations, challenging communications environments and varying customer densities in different areas of the service territory.

Those communications and connectivity challenges continue from deployment into the operational phase when critical business processes – such as customer billing, grid operations and a rapidly expanding set of smart grid applications – are dependent on the reliability, speed and manageability of the network.

Eliminating compromises

Until now utilities have had to:

- a) Choose the best-fit, single communication technology to provide the most effective coverage for most of the territory. Then struggle through with the remainder.
- b) Deploy 'hybrid' solutions that comprise multiple communication networks each best suited to specific geographies or customer densities.

Hybrid approaches typically present significant integration and operational challenges with multiple head-ends and networks, which increases the cost of ownership and complexity, and requires significantly more resources to plan, operate and maintain the network. With current communication technologies, achieving optimal connectivity and performance throughout the territory invariably increases ownership costs.

Envision the ideal

What if utilities could deploy a network that incorporated two communications technologies – radio frequency (RF) and power line carrier (PLC) – on the same chip or module? And no matter what, that module would always choose and utilize the fastest and most reliable

communication path, and most appropriate modulation scheme based on its location, network operating conditions and the nature of the application or data. And what if this happened dynamically, intelligently and continuously at all levels of the network, for every link, every message, and every device?

In fact, the network operator wouldn't even have to know, and doesn't even need to care, which

physical transport was in use. Instead, he could just monitor the network through a 'single-pane' network management system (NMS) with supreme confidence that the network would perform and deliver.

Adaptive Communications Technology

In August, Itron previewed its new adaptive communications technology, or ACT, which is being installed initially and piloted at CLP Power in Hong Kong. CLP Power is the first utility to test Itron's ACT, which combines RF and PLC communications in the same device. Hong Kong's urban environment with many high-rise buildings and enclosed meter rooms presents a number of network connectivity challenges for any smart grid solution.

Itron's ACT combines RF mesh and PLC communications on the same chip set, which is powered by an advanced microcontroller running a Linux-based operating system. This enables dynamic selection of the optimal communications path and frequency modulation based on network operating conditions, data attributes and application requirements. With adaptive communication capabilities, deployment of network infrastructure is easier, faster and less costly. It also reduces the amount of time and effort needed for upfront network design and propagation studies. Itron is first in bringing this new technology to the market to address the deployment and network performance challenges presented by dense, urban environments and diverse service territories.

With these new edge intelligence capabilities, meters and other grid devices can process, analyze, communicate and react in real-time; intelligently switching communication modes between PLC and RF to provide optimal network performance with assured connectivity.

With adaptive communications, Itron has delivered a game-changing, standards-

Itron's Adaptive Communications Technology for OpenWay:

- RF Mesh and Power Line Carrier (PLC) on every communications module
- Network dynamically self-selects best communication path
- Assured connectivity at highest possible speed
- Simplified "zero-touch" deployment and reduced infrastructure
- Lower total of ownership
- Performance to support smart grid and smart cities applications
